

Process for Converting Waste Biomass

Tech ID: 18696 / UC Case 2008-516-0

ABSTRACT

A researcher at the University of California, Davis has developed a chemical approach for the total conversion of plant carbohydrates to biofuels and value-added products.

FULL DESCRIPTION

A researcher at the University of California, Davis has developed a process for converting waste biomass (agricultural, municipal forestry) into 5-chlorofurfural (CMF) in yields approaching 90% of the theoretical. Thus far no other method of biomass deconstruction gives such a high conversion to a simple organic product. The process is completely chemical in nature and inexpensive. Conditions are mild ($T \leq 100$ °C) and reaction times are short (≤ 4 h). By reaction with ethanol or hydrogen, the CMF product is converted into 5-ethoxymethyl furfural and 5-methylfurfural, respectively, both of which are promising biofuel candidates, and the former of which is currently being commercialized in Europe as a diesel additive. By reaction with water, the CMF product is converted into levulinic acid, an industrially important value-added chemical. A secondary product of this process is furfural itself, which derives from the hemicellulose content of plant biomass. Furfural is currently traded as a commercial commodity.

APPLICATIONS

- High yield process for the development and manufacture of renewable alternative fuels

FEATURES/BENEFITS

- More efficient than conventional ethanol production
- Direct utilization of cellulose, a prevalent and available source of carbon
- Derived biofuels are hydrophobic, non-toxic, non-volatile, non-corrosive, clean-burning, and biodegradable
- Method can be used to derive either biofuels or value added materials from biomass
