

Smart Materials Capable of Programmed Shape Change

Tech ID: 20952 / UC Case 2010-007-0

BACKGROUND

Nanoparticles capable of reversible changes in morphology in response to specific stimuli are expected to have broad utility in designing targeted drug-delivery, detection strategies, self-healing materials, and templates for hierarchical directed assembly. While there are several elegant examples of stimuli-responsive soft nanoparticles, programmable materials with the requisite shape-change properties remain elusive.

TECHNOLOGY DESCRIPTION

UC San Diego researchers have developed soft nanoparticle materials that exhibit reversible, stimuli-responsive changes in morphology. In its primary embodiment, the invention leverages the utility of DNA as an informational molecule to design nanoparticles that undergo reversible morphological changes in a DNA-encoded fashion. Utilizing the sequence selective recognition properties of DNA, and its performance as a substrate for selective enzymatic cleavage, the amphiphilicity of a range of surfactants is programmed and tuned. This approach provides unprecedented programmability and reversible control over the morphology of nanoscale objects and allows user-defined selection of particle shapes and sizes. Control over these materials and their utility in detection, reversible uptake/release, and as soft material templates have been demonstrated. Another inventive aspect provides peptide-based enzymatic responsive systems.

APPLICATIONS

The invention has a wide range of biomedical and device applications including phase-change triggered drug delivery, morphology-controlled pharmacokinetics, phase-change activated MRI contrast agents, and biotemplating of materials for nanoelectronics.

INTELLECTUAL PROPERTY INFO

This technology has a patent pending and is available for sponsorship and/or licensing.
