Formation of Polymers on Nanostructures Under X-ray Irradiation

Tech ID: 22908 / UC Case 2013-325-0

ABSTRACT

First time demonstration of enhanced formation of polymers on nanostructures under X-ray irradiation.

FULL DESCRIPTION

Researchers at UC Davis have developed methods of formation of a polymer from a monomer on a metal-based nanoparticle under X-ray irradiation or the dissolution of metal ions from this nanoparticle under X-ray irradiation, and more specifically methods of enhancing formation of a polyaniline polymer from an aniline monomer on a silver core - gold shell nanoparticle under X-ray irradiation and release of Ag ions from this core-shell nanoparticle. X-rays are highly penetrating, and nanomaterials can pinpoint the growth of polymers down to nanometer scale. Therefore it is possible to use short wavelength X-rays and nanomaterials to create high precision polymer structures of nanometer resolution.

APPLICATIONS

- ▶ Use of short wavelength X-rays and nanomaterials to create high precision polymer structures of nanometer resolution can potentially be used by drug, semiconductor and sensor industry
- ▶ X-ray triggered release of Ag ions can function as targeted antimicrobial release

FEATURES/BENEFITS

- ▶ Uses nanostructures and wide beam X-rays to make nanostructures of polymers
- ▶ Alternative method of making photomasks

PATENT STATUS

Country	Type	Number	Dated	Case
United States Of America	Issued Patent	9,718,922	08/01/2017	2013-325
