Silent Speech Interface Using Manifold Decoding Of Biosignals

Tech ID: 33771 / UC Case 2024-594-0

ABSTRACT

Researchers at the University of California, Davis have developed a technology that provides a novel method for decoding biosignals into speech, enhancing communication for individuals with speech impairments.

FULL DESCRIPTION

The technology involves a computer-implemented method and system for decoding biosignals (e.g., those indicative of orofacial movements) into speech. It utilizes a unique approach that reduces the computational complexity, and thus the amount of time needed, to decode biosignals and translate them into synthesized speech.

APPLICATIONS

- Assistive technologies for individuals with speech impairments due to ALS, stroke, cancer, and other conditions.
- ▶ Human-computer interaction systems that require robust speech recognition capabilities.
- ▶ Medical devices and applications focused on rehabilitation and communication restoration.
- ▶ Can be used to decode/translate a wide variety of biosignals that are recorded from patients.

FEATURES/BENEFITS

- Addresses the variability of biosignals across individuals and sessions, enhancing accuracy and robustness.
- ▶ Reduces the computational demand and need for extensive retraining typically associated with neural network-based approaches.
- ▶ Improves accessibility for individuals with speech impairments due to various causes, including neurological diseases and physical damage.
- ▶ Facilitates real-time communication by efficiently decoding complex biosignals into speech.
- ▶ Overcomes communication barriers faced by individuals with dysarthria, dysphonia/aphonia, and other speech impairments.
- Addresses the challenge of signal variability due to individual anatomical and physiological differences.
- ▶ Reduces the high computational cost and inefficiency of existing neural network approaches in adapting to new individuals.
