Relationship Between Zsm-5 Pore Modifications And Gallium Proximity And Liquid Hydrocarbon Number Distribution From Ethanol Oligomerization

Tech ID: 32771 / UC Case 2022-867-0

PATENT STATUS

Patent Pending

FULL DESCRIPTION

Background

A particularly promising route that could facilitate rapid transformation of biomass to low carbon emission aviation fuel, is catalytic conversion of ethanol into Sustainable Aviation Fuel (SAF) that meets energy density and other fit-for-purpose requirements. Many of the alcohol to jet processes that are currently being scaled up require 3 to 4 catalytic steps, require high temperatures and pressures and can suffer from compounding of losses in yield at each step. Recent research studies have indicated that Gallium (Ga) addition to H-ZSM-5 (the protonic or H-type Zeolite Socony Mobil – a catalyst) increased the production of Benzene/Toluene/Xylene (BTX). However, in these cases most of the gallium oxide was shown to be on the zeolite external surface. Reports have indicated that Ga inside the H-ZSM-5 pores enhanced BTX selectivity.

Current Invention

Researchers at UCR have developed a novel, simple synthesis for enhancing the insertion of Ga into the zeolite channels. The invention has successfully demonstrated that enhancing the zeolite pore volumes resulted in longer hydrocarbon chain lengths that are desirable for aviation fuels. Specifically, in their invention, H-ZSM-5 supports were desilicated by treatment with sodium hydroxide (NaOH) to produce mesopore-crystalline H-ZSM-5. Gallium was loaded onto the modified ZSM-5 supports by following incipient wet impregnation procedures and the resulting catalysts were used to catalyze ethanol conversions.

Effect of (a) catalyst synthesis time and (b) Ga content on liquid hydrocarbon product selectivity following reaction of ethanol on Ga(5 wt. %)/ZSM-5 catalysts at 350°C with a 0.4h⁻¹ WHSV. Product selectivity is based on total liquid hydrocarbons.

ADVANTAGES

The significant benefits/advantages of their invention are:
A single step process for bioethanol conversion to jet fuel blendstocks (C9+ hydrocarbons) using Ga/modified ZSM-5 supports.

By modifying the ZSM-5 pores, we can now migrate Ga into the zeolite channels and consequently the ethanol product distributions and specifically liquid hydrocarbon yields.

Optimized process for zeolite pore size, crystallinity and Ga loading to achieve higher selectivity of C9-C10 hydrocarbons and catalyst stability (over 32 hours).

For the first time, we now have the ability to achieve ≥ 50% selectivity of C9-C10 hydrocarbons and ≥50% liquid hydrocarbons yield from ethanol and wet-ethanol conversions.

ZSM-5 modification with NaOH results in catalysts that can now be applied for ethanol conversion to C9-C10 hydrocarbons.

SUGGESTED USES

For the conversion of bioethanol to sustainable aviation fuel.
