Self-Regenerative Ni-Doped Catio3/Cao For Co2 Capture And Utilization

Tech ID: 33607 / UC Case 2024-705-0

PATENT STATUS

Patent Pending

FULL DESCRIPTION

Background

Integrated CO\textsubscript{2} capture and dry reforming of methane (ICCDRM) is a process that tackles two important greenhouse gases - CO\textsubscript{2} and methane (CH\textsubscript{4}) - transforming them into useful syngas. Nickel/Calcium Oxide (Ni/CaO) based dual functional materials (DFM) are widely evaluated for integrated CO\textsubscript{2} capture and utilization (ICCU), especially in processes like dry reforming of methane (DRM), where CO\textsubscript{2} and CH\textsubscript{4} are converted into syngas. However, these conventional systems face significant challenges resulting in significant reduction in CO\textsubscript{2} capture and overall efficiency of ICCDRM, especially because of:

▶ Coke deposition on the Ni catalyst that reduces the efficacy of the catalyst; and,
▶ Stability of CaO resulting in pore collapse, surface area loss and/or agglomeration of Ni nanoparticles.

Invention

Prof. Abdul-Aziz and her team at UCR have developed a novel multifunctional material (MFM) designed to enhance the efficiency and stability of ICCDRM processes. The team successfully synthesized Ni-doped CaTiO\textsubscript{3}/CaO nanocomposite, addressing key challenges associated with conventional Ni/CaO systems. The MFM effectively addresses the limitations of conventional systems, showcasing its potential for practical applications in carbon capture and utilization.

Schematic representation of the ICCDRM process
Comparison of the effectiveness of the MFM in CO$_2$ and H$_2$ production.

**ADVANTAGES**

- Enhanced CO$_2$ capture capacity and stability
- Improved catalytic activity and stability
- Self-regeneration of Ni nanoparticles
- Mitigation of coke deposition

**SUGGESTED USES**

Capture and reformation of greenhouse gases, Carbon Dioxide and Methane - and the conversion to valuable syngas.

**INVENTOR INFORMATION**
